1. INTRODUCTION AND PRELIMINARIES

Let \( H \) be an infinite dimensional complex Hilbert space and \( B(H) \) denote the algebra of all bounded linear operators acting on \( H \). Every operator \( T \) can be
decomposed into $T = U |T|$ with a partial isometry $U$, where $|T| = \sqrt{T^*T}$. In this paper, $T = U |T|$ denotes the polar decomposition satisfying the kernel condition $N(U) = N(|T|)$. An operator $T$ is said to be positive if $(Tx, x) \geq 0$ for all $x \in H$. An operator $T$ is said to be a $p$-hyponormal operator if and only if $(T^*T)^p \geq (TT^*)^p$ for a positive number $p$.

In [22], the class of log-hyponormal operators is defined as follows: $T$ is called log-hyponormal if it is invertible and satisfies $\log(T^*T)^p \geq \log(TT^*)^p$. Class of $p$-hyponormal operators and class of lg hyponormal operators were defined as extension class of hyponormal operators, i.e., $(T^*T) \geq (TT^*)$. It is well known that every $P$-hyponormal operator is a $q$-hyponormal operator for $p \geq q > 0$, by the Lowner-Heinz theorem $A \geq B \geq 0$ ensures $A^\alpha \geq B^\alpha$ for any $\alpha \in [0,1]$, and every invertible $p$-hyponormal operator is a log-hyponormal operator since $\log(.)$ is an operator monotone function. An operator $T$ is called paranormal if $\|T^2x\|^2 \leq \|T^2x\| \|x\|$ for all $x \in H$. It is also well known that there exists a hyponormal operator $T$ such that $T^2$ is not hyponormal (see [12]).

Furuta, Ito and Yamazaki [7] introduced class $A(K)$ and absolute - $k$- paranormal operators for $k > 0$ as generalizations of class $A$ and paranormal operators, respectively. An operator $T$ belongs to class $A(K)$ if $(T^*|T|^{2K}T)^{\frac{1}{k+1}} \geq |T|^2$ and $T$ is said to be absolute -$k$- paranormal operator if $\|T^kTx\| \leq \|T\|^{k+1}$ for every unite vector $x$. An operator $T$ is called quasi class $A$ if $T^*|T|^2T \geq T^*|T|^2T$.

Fuji, Izumino and Nakamoto [9] introduced $p$-paranormal operators for $p > 0$ as a generalization of paranormal operators. An operator $T \in class A(p, r)$ for $p > 0$ and $r > 0$ if $\left( |T^*| |T|^{2p} |T^*| \right)^{\frac{1}{p+r}} \geq |T^*|^{2r}$ and class $AI(p, r)$ is class of all invertible operators which belong to class $A(p, r)$. Yamazaki [24] introduced absolute-$(p, r)$-paranormal operator. It is a further generalization of the classes of both absolute-$k$-paranormal operators and $p$-paranormal operators as a parallel concept of class $A(p, r)$. An operator $T$ is said to be paranormal operator if $\|T^2x\| \geq \|Tx\|^2$ for every unit vector $x$. Paranormal operators have been studied by many authors [2], [8] and [16].

In [2], Ando showed that $T$ is paranormal if and only if $T^*^2T^2 - 2\lambda T^*T + \lambda^2 \geq 0$ for all $\lambda > 0$.

In order to extend the class of paranormal operators and class of quasi-class $A$ operators, Mecheri introduced a new class of operators called $k$-
quasi-paranormal operators. An operator $T$ is called $k$-quasi-paranormal if
\[ \|T^{k+1}x\|^2 \leq \|T^{k+2}x\|\|T^kx\| \]
for all $x \in H$ where $k$ is a natural number. A 1-quasi-paranormal operator is quasi paranormal.

The following implication give us relations among the class of operators.

Hyponormal $\Rightarrow$ $p$-hyponormal $\Rightarrow$ class $A$ $\Rightarrow$ paranormal $\Rightarrow$ quasi-paranormal $\Rightarrow$ $k$-quasi-paranormal.

Hyponormal class $A$ $\Rightarrow$ paranormal $\Rightarrow$ quasi-paranormal $\Rightarrow$ $k$-quasi-paranormal.

An operator $T \in B(H)$ is said to be $*$-paranormal operator if
\[ \|T^*x\|^2 \leq \|T^2x\|^2 \]
for every unit vector $x$. Hyponormal operators are paranormal and $*$-paranormal. The clas of $*$-paranormal operators was defined by S. M. Patel. In order to extend the class of paranormal and $*$-paranormal operators Mecheri introduced the class of quasi $*$-paranormal operators. An operator $T$ is called quasi $*$-paranormal operator if
\[ \|T^*T^3x\|^2 \leq \|T^3x\|^2 \|T^2x\| \]
for every $x \in H$. An operator $T$ is quasi $*$-paranormal if and only if $T^*T^3 - 2\lambda(T^*T)^2 + \lambda^2T^*T \geq 0$ for all $\lambda > 0$. Every $*$-paranormal operator is quasi $*$-paranormal and we have the following implication:

Hyponormal $\Rightarrow$ $*$-paranormal $\Rightarrow$ quasi $*$-paranormal.

Let $(X, \sum, \lambda)$ be a sigma-finite measure space and let $T : X \rightarrow X$ be a non singular measurable transformation. A bounded linear operator $Cf = f \circ T$ on $L^2(X, \sum, \lambda)$ is said to be a composition operator induced by $T$, when the measure $\lambda T^{-1}$ is absolutely continuous with respect to the measure $\lambda$ and the Radon-Nikodym derivative $d\lambda T^{-1}/d\lambda = f_0$ is essentially bounded. The Radon-Nikodym derivative of the measure $\lambda(T^k)^{-1}$ with respect to $\lambda$ is denoted by $f_0^k$, where $T^k$ is obtained by composing $T$ - k times.

**Theorem 1.** Let $T \in B(H)$ be an operator of quasi $*$-paranormal. Then if $T$ is unitarily equivalent to $S$. The $S$ is of quasi $*$-paranormal.

**Proof.** Since $T$ is unitarily equivalent to $S$. There is an unitarily operator $U$ such that $S = U^*TU$. We must show that $S^*^3S^3 - 2\lambda(S^*S)^2 + \lambda^2S^*S \geq 0$.Since $T$ is of quasi $*$-paranormal, we have $T^*^3T^3 - 2\lambda(T^*T)^2 + \lambda^2T^*T \geq 0$. 
Hence \( S^*S^3 - 2\lambda(S^*S)^2 + \lambda^2 S^*S \geq 0 \)

\[
\{(U^*T^*U)(U^*T^*U)(U^*T^*U)(U^*T^*U)(U^*T^*U)\} \\
- 2\lambda \{(U^*T^*U)(U^*T^*U)\}^2 + \lambda^2 \{(U^*T^*U)(U^*T^*U)\} \geq 0,
\]

\[
U^* \{T^*T^3 - 2\lambda(T^*T)^2 + \lambda^2 T^*T \} U \geq 0.
\]

Therefore \( S \) is quasi *- paranormal. \( \square \)

**Theorem 2.** Let \( T \in B(H) \) be a weighted shifted with with non zero weight \( \{\alpha_n\} (n = 0, 1, 2, 3, ...). \) Then \( T \) is of quasi *- paranormal if and only if \( |\alpha_n|^2 \leq |\alpha_{n+1}| |\alpha_{n+2}| \) for \( n = 1, 2, 3, .. \)

**Proof.** Let \( \{\alpha_n\}_{n=0}^\infty \) be an orthogonal basis of a Hilbert space \( H. \) Since \( Te_n = \alpha_n e_{n+1} \) and \( T^n e_n = \bar{\alpha}_{n-1} e_{n-1} \), we have

\[
\|T^*T e_n\|^2 = \|T^*(\alpha_n e_{n+1})\|^2 \\
= |\alpha_n|^2 \|T^* e_{n+1}\|^2 \\
= |\alpha_n|^2 |\bar{\alpha}_{n-1}|^2 \|e_n\|^2 \\
= |\alpha_n|^4.
\]

and \( \|T^3 e_n\| \|T e_n\| = |\alpha_n|^2 |\alpha_{n+1}| |\alpha_{n+2}|. \) We see that \( T \) is of quasi *- paranormal if and only if \( |T^*T x|^2 \leq \|T^3 x\| \|T x\| \) for each vector \( x \in H \) if and only \( \|T^*T e_n\|^2 \leq \|T^3 e_n\| \|T x\| \) for each \( n = 1, 2, 3, ... \) Hence \( T \) is of quasi *- paranormal if and only if \( |\alpha_n|^2 \leq |\alpha_{n+1}| |\alpha_{n+2}| \) for \( n = 1, 2, 3, .. \) \( \square \)

**2. QUASI *- PARANORMAL COMPOSITION OPERATORS**

In this section, we characterize quasi *- paranormal composition operator. Every essentially bounded complex valued measurable function \( f_0 \) induces the bounded operator \( M_{f_0} \) on \( L^2(\lambda) \), which is defined \( M_{f_0} f = f_0 f \) for every \( f \in L^2(\lambda) \). Further \( C^*C = M_{f_0} \) and \( C^*2C^2 = M_{f_0^{(2)}} \).

The following Theorem due to Harrington and Whitely is well known.

**Theorem 3.** If \( P \) denote the projection of \( L^2 \) on \( \overline{R(C)} \), then \( C^*C f = f_0 f \) and \( C^*C f = (f_0 \circ T)P f \) for all \( f \in L^2(\lambda) \) where \( P \) denote the projection \( L^2 \) onto \( \overline{R(C)} \) and \( R(C) = \{ f \in L^2 : f is T^{-1} \sum \text{measurable} \}. \)
The following theorem characterize quasi ∗- paranormal composition operators on $L^2$ space.

**Theorem 4.** Let $C \in B \left( L^2(\lambda) \right)$. Then $C$ is of quasi ∗- paranormal operator if and only if $f_0^{(3)} - 2\lambda f_0^{(2)} + \lambda^2 f_0 \geq 0$, a.e, where $P$ denote the projection $L^2$ onto $R(C)$.

**Proof.** Let $C \in B \left( L^2(\lambda) \right)$. Then $C$ is of quasi ∗- paranormal operator if and only if

$$C^* C^3 - 2\lambda (C^* C)^2 + \lambda^2 C C^* \geq 0$$

Thus,

$$\langle (C^* C^3 - 2\lambda (C^* C)^2 + \lambda^2 C C^*) \chi_E, \chi_E \rangle \geq 0$$

for every characteristic function $\chi_E$ in $\sum$ such that $\lambda(E) < \infty$. Since $C^* C^2 = M_{f_0^{(2)}}$, $C^* C = M_{f_0}$, we have

$$\langle (M_{f_0^{(3)}} - 2\lambda M_{f_0^{(2)}} + \lambda^2 M_{f_0}) \chi_E, \chi_E \rangle \geq 0,$$

$$\int_E (f_0^{(3)} - 2\lambda f_0^{(2)} + \lambda^2 f_0) \geq 0,$$

for every $E$ in $\sum$. Hence $C$ is of quasi ∗- paranormal operator if and only if $f_0^{(3)} - 2\lambda f_0^{(2)} + \lambda^2 f_0 \geq 0$ a.e. \qed

**Corollary 5.** Let $C \in B \left( L^2(\lambda) \right)$ with dense range. Then $C$ is of quasi ∗- paranormal operator if and only if $f_0^{(3)} - 2\lambda f_0^{(2)} + \lambda^2 f_0 \geq 0$, a.e.

**Example 6.** Let $X = N$, the set of all natural number and $\lambda$ be the counting measure on it. Define $T : N \to N$ by $T(1) = 1$, $T(n+m+1) = n$, $m = 0, 1, 2, ..$, and $n \in N$. Since $f_0^{(3)} - 2\lambda f_0^{(2)} + \lambda^2 f_0 \geq 0$, $C$ is of quasi ∗- paranormal composition operator.

**Theorem 7.** Let $C \in B \left( L^2(\lambda) \right)$. Then $C^*$ is of quasi ∗- paranormal operator if and only if $[(f_0 \circ T)^{(3)} P] - 2\lambda [(f_0 \circ T)^{(2)} P] + \lambda^2 [(f_0 \circ T) P] \geq 0$, a.e, where $P$ denote the projection $L^2$ onto $R(C)$.

**Proof.** Then $C^*$ is of quasi ∗- paranormal operator if and only if

$$C^3 C^* - 2\lambda (CC^*)^2 + \lambda^2 CC^* \geq 0,$$
\[ \langle (C^* C^3 - 2\lambda (C^* C)^2 + \lambda^2 C^* C) f, f \rangle \geq 0. \]

We have \( \langle CC^* f, f \rangle = \langle (f_0 pf, f) \rangle \) where \( P \) denote the projection \( L^2 \) onto \( \overline{R(C)} \). Thus \( C^* \in \text{quasi } \ast \text{- paranormal operator if and only if} \)

\[ \left( \langle (f_0 \circ T)_{(3)} P \rangle - 2\lambda[(f_0 \circ T)_{(2)} P] + \lambda^2[(f_0 \circ T)P] f, f \rangle \right) \geq 0, \]

a.e, for every \( f \in L^2 \), i.e.

\[ [(f_0 \circ T)_{(3)} P] - 2\lambda [(f_0 \circ T)_{(2)} P] + \lambda^2 [(f_0 \circ T)P] \geq 0, \text{ a.e.} \]

\[ \square \]

**Theorem 8.** Let \( C^* \in B \left( L^2(\lambda) \right) \) with dense range. Then \( C^* \in \text{quasi } \ast \text{- paranormal operator if and only if} \)

\[ [(f_0 \circ T)_{(3)} P] - 2\lambda [(f_0 \circ T)_{(2)} P] + \lambda^2 [(f_0 \circ T)P] \geq 0, \text{ a.e.} \]

### 3. WEIGHTED QUASI \( \ast \)-PARANORMAL COMPOSITION OPERATORS

A weighted composition operator (w.c.o) induced by \( T \) is a linear transformation acting on the set of complex valued \( \sum \) measurable function \( f \), defined as \( W f = w(f \circ T) \), \( w \) is a complex valued \( \sum \) measurable function. when \( w = 1 \), we say that \( W \) is a composition operator. Let \( w_k \) denote \( w(w \circ T)(w \circ T^2) \ldots \ldots (w \circ T^{k-1}) \) so that \( W_k f = w_k (f \circ T)^k \). To examine the weighted quasi \( \ast \)-paranormal composition operators effectively Alan Lambert associated conditional expectation operator \( E \) with \( T \) as \( E(./T^{-1} \sum) = E(.) \). \( E(f) \) is defined for each non-negative measurable function \( f \in L^p(1 \leq p) \) and is uniquely determined by the conditions:

(i) \( E(f) \) is \( T^{-1} \sum \) measurable.

(ii) If \( B \) is any \( T^{-1} \sum \) set for which \( \int_B f d\lambda \), we have \( \int_B f d\lambda = \int_B E(f) d\lambda \).

The projection operator \( E \) on \( L^p \) is identity if and only if \( T^{-1} \sum = \sum \).

**Proposition 9.** For \( w \geq 0 \):

(i) \( W^* W f = f_0[E(w^2)] \circ T^{-1} f \).

(ii) \( WW^* f = w(f_0 \circ T)E(wT) \).
Now we characterize weighted quasi $\ast$-paranormal composition operators as follows.

**Theorem 10.** $W$ is quasi $\ast$-paranormal if and only if
\[ f_0^{(3)}[E(w_3^2)] \circ T^{-3} - 2\lambda \{ f_0[E(w^2)] \circ T^{-1} \}^2 + \lambda^2 f_0[E(w^2)] \circ T^{-1} \geq 0, \text{ a.e.} \]

**Proof.** $W$ is of quasi $\ast$-paranormal operator if and only if
\[ W^*W - 2\lambda(W^*W)^2 + \lambda^2 W^*W \geq 0 \]
and hence,
\[ \langle (W^*W^3 - 2\lambda(W^*W)^2 + \lambda^2 W^*W), f, f \rangle \geq 0 \]
for all $f \in L^2$. Since $W^k f = w_k(f \circ T^k)$ and $W^k f = f_0^{(k)}[E(w_k^2)] \circ T^{-k}$, $W^k W^k = f_0^{(k)}[E(w_k^2)] \circ T^{-1} f$ and we have $W^*W f = f_0[E(w^2)] \circ T^{-1} f$ for $w \geq 0$, and hence
\[
\int_E \left\{ f_0^{(3)}[E(w_3^2)] \circ T^{-3} - 2\lambda \{ f_0[E(w^2)] \circ T^{-1} \}^2 + \lambda^2 f_0[E(w^2)] \circ T^{-1} \right\} d\lambda \\
\geq 0,
\]
for every $E \in \Sigma$. And so
\[ f_0^{(3)}[E(w_3^2)] \circ T^{-3} - 2\lambda \{ f_0[E(w^2)] \circ T^{-1} \}^2 + \lambda^2 f_0[E(w^2)] \circ T^{-1} \geq 0 \text{ a.e.} \]

**Corollary 11.** Let $L^{-1} \Sigma = \sum W$ is of quasi $\ast$-paranormal operator if and only if $f_0^{(3)}(w_3^2) \circ T^{-3} - 2\lambda \{ f_0(w^2) \circ T^{-1} \}^2 + \lambda^2 f_0(w^2) \circ T^{-1} \geq 0$ a.e.

The Aluthge transform of $T$ is the operator $\tilde{T}$ given $\tilde{T} = |T|^{\frac{1}{2}} U |T|^{\frac{1}{2}}$ introduced in [1] by Aluthge is the Aluthge transform of $T$. The idea behind the Aluthge transform is to convert an operator into another operator which shares with the first one some spectral properties but it is closed to being a normal operator. More generally we may have family of operators $T_s : 0 < s \leq 1$ where $T_s = |T|^s U |T|^{1-s}$. For the composite operator $C$, the polar decomposition is given $C = U |C|$ where $|C| f = \sqrt{f_0} f$ and $U f = \frac{1}{\sqrt{f_0}} f \circ T$. [2] Lambert has given general Aluthge transformation for composition operator as $C_s = |C|^s U |C|^{1-s}$ and $C_s f = \left( \frac{f_0}{\sqrt{f_0} T} \right)^\frac{s}{2} f \circ T$. That is $C_s$ is the weighted composite multiplicative operator with weight $\pi = \left( \frac{1}{\sqrt{f_0} T} \right)^\frac{s}{2}$ where $0 < s < 1$. 

Since $C_r$ is weighted composite multiplication operator it is easy to show that $|C_s| = \sqrt{f_0[E(\pi)^2 \circ T^{-1}]} f$ and $|C_s^*| f = \nu E[\nu f]$ where $\nu = \frac{\pi\sqrt{f_0 \circ T}}{[E(\pi)\sqrt{f_0 \circ T}^2]^2}$.

**Proposition 12.** For every $n \in \mathbb{N}$:

(i) $C_r^k f = \pi_k \cdot (f \circ T^k)$.

(ii) $C_r^{*k} f = f_0^k \cdot (E_{\pi_k} f) \circ T^{-k}$.

(iii) $C_r^{*k} C_r^k f = f_0^k \cdot E(\pi_k^2) \circ T^{-k} f$.

**Corollary 13.** Let $L^{-1} \sum = \sum$, $C_s \in B(L^2(\lambda))$. Then $C_s$ is of quasi *-paranormal operator if and only if $f_0^{(3)}(\pi_3^2) \circ T^{-3} - 2\lambda \left\{ f_0(\pi^2) \circ T^{-1} \right\}^2 + \lambda^2 f_0(\pi^2) \circ T^{-1} \geq 0$ a.e.

**Proof.** Since $C_s$ is of quasi *-paranormal operator with weight $\pi = \left( \frac{f_0}{f_0 \circ T} \right)^{\frac{s}{2}}$ it follows that $C_s$ is of quasi *-paranormal operator if and only if $f_0^{(3)}(\pi_3^2) \circ T^{-3} - 2\lambda \left\{ f_0(\pi^2) \circ T^{-1} \right\}^2 + \lambda^2 f_0(\pi^2) \circ T^{-1} \geq 0$ a.e. \[ \square \]

The second Aluthge Transformation $T$ described by B.P. Duggle is given by $\hat{T} = \left| \hat{T} \right|^\frac{1}{2} V \left| \hat{T} \right|^{\frac{1}{2}}$ and $\left| \hat{T} \right| = V \left| \hat{T} \right|$ is the polar decomposition of $\left| \hat{T} \right|$. Senthilkumar and Prasad studied that the operator $\hat{C} = \left| \hat{C} \right|^\frac{1}{2} V \left| \hat{C} \right|^{\frac{1}{2}}$ and $\left| \hat{C} \right| = V \left| \hat{C} \right|$ is the polar decomposition of $\left| \hat{C} \right| : 0 \leq s \leq 1$ is weighted composition operator with weight $w' = J\frac{1}{\pi} \left( \frac{X_{sup}^J}{J^2} \circ T \right)$ where $J = f_0 E(\pi^2) \circ T^{-1}$

**Corollary 14.** Let $L^{-1} \sum = \sum$, $\hat{C} \in B(L^2(\lambda))$. Then $\hat{C}$ is of quasi *-paranormal operator if and only if

$$f_0^{(3)}(w_3') \circ T^{-3} - 2\lambda \left\{ f_0(w') \circ T^{-1} \right\}^2 + \lambda^2 f_0(w') \circ T^{-1} \geq 0,$$

a.e.

**Proof.** Since $\hat{C}$ is of quasi *-paranormal operator with weight

$$w' = J\frac{1}{\pi} \left( \frac{X_{sup}^J}{J^2} \circ T \right),$$

it follows that $\hat{C}$ is of quasi *-paranormal operator if and only if $f_0^{(3)}(w_3') \circ T^{-3} - 2\lambda \left\{ f_0(w') \circ T^{-1} \right\}^2 + \lambda^2 f_0(w') \circ T^{-1} \geq 0$ a.e. \[ \square \]
4. QUASI *- PARANORMAL COMPOSITION OPERATORS ON WEIGHTED HARDY SPACES

The set $H^2(\gamma)$ of formal complex power series $f(z) = \sum_{n=0}^{\infty} a_n Z^n$ such that $\|f\|_\gamma^2 = \sum_{n=0}^{\infty} |a_n|^2 \gamma_n^2 < \infty$ is the general Hardy space of functions analytic in the unit disc with inner product $\langle f, g \rangle_\gamma = \sum_{n=0}^{\infty} a_n b_n \gamma_n^2$ for $f$ as above and $g(z) = \sum_{n=0}^{\infty} b_n Z^n$ and $\gamma = \{\gamma_n\}_{n=0}^{\infty}$ be a sequence of positive number with $\gamma_0 = 1$ and $\frac{\gamma_{n+1}}{\gamma_n} \to 1$ as $n \to \infty$.

If $\phi$ is an analytic function mapping the unit disc $D$ into itself, we define the composition operator $C_\phi$ on the spaces $H^2(\gamma)$ by $C_\phi = f_\phi$. Though the operator $C_\phi$ are defined everywhere on the classical Hardy space $H^2$, they are not necessarily defined on all of $H^2(\beta)$. The composition operator $C_\phi$ is defined $H^2(\gamma)$ only when the function $\phi$ is analytic function on some open set containing the closed unit disc having supremum norm strictly smaller than one.

The properties of composition operator on the general Hardy spaces $H^2(\gamma)$ are studied. In this section, we investigate the properties of $k$- quasi - paranormal composition operators on general Hardy space $H^2(\gamma)$.

For a sequence $\gamma$ as above and a point $w$ in $D$, let $k_w \gamma(z) = \sum_{n=0}^{2} \frac{1}{\gamma_2} (wz)^n$. Then the function $k_w \gamma$ is a point evaluation $H^2(\gamma)$ i.e., for $f \in H^2(\gamma), (f, k_w \gamma) = f(w)$.

Then $k_0 \gamma = 1$ and $C^*k_w \gamma = k_{\phi(w)} \gamma$.

**Theorem 15.** If $C_\phi$ is quasi * - paranormal on $H^2(\gamma)$ then $\|k_\gamma\|_\gamma^2 - 1 \geq 0$

**Proof.** Let $C_\phi$ is quasi * - paranormal on $H^2(\gamma)$. By the definition of quasi * - paranormal,

$$C^3 \phi C^3 - 2\lambda(C^* \phi C_\phi)^2 + \lambda^2 C^* \phi C_\phi \geq 0,$$

$$\langle (C^3 \phi C_\phi^3 - 2\lambda(C^* \phi C_\phi)^2 + \lambda^2 C^* \phi C_\phi) f, f \rangle \geq 0,$$

$$\langle (C^3 \phi C_\phi^3 f, f) \rangle - 2 \langle (\lambda(C^* \phi C_\phi)^2 f, f) \rangle + \lambda^2 \langle (C^* \phi C_\phi) f, f \rangle \geq 0,$$

$$\|C^3 \phi f\|^2 - 2\lambda \|C^* \phi C_\phi f\|^2 + \lambda^2 \|C_\phi f\|^2 \geq 0,$$

$$\|C^2 \phi (C_\phi f)\|^2 - 2\lambda \|C^* \phi (C_\phi f)\|^2 + \lambda^2 \|C_\phi f\|^2 \geq 0,$$

$$\|C^2 \phi(C_\phi k_0 \gamma)\|^2 - 2\lambda \|C^* \phi(C_\phi k_0 \gamma)\|^2 + \lambda^2 \|C_\phi k_0 \gamma\|^2 \geq 0,$$
\[ \| C_\phi^2(k_0\gamma) \|^2 - 2\lambda \| C_\phi^*(k_0\gamma) \|^2 + \lambda^2 \| k_0\gamma \|^2 \geq 0. \]

Repeating the steps for 2 more we get

\[ \|(k_0\gamma)\|\|^2 - 2\lambda \|(k_0\gamma)\|^2 + \lambda^2 \| k_0\gamma \|^2 \geq 0, \]

\[ 1 - 2\lambda \| k_\phi^*(\gamma) \|_{\gamma}^2 + \lambda^2 \geq 0. \]

By elementary properties of real quadratic form we get \[ \| k_\phi^*(\gamma) \|_{\gamma}^2 - 1 \geq 0. \]
